Dynamic Events

CSV Specifications

2024/07/12

Changelog since 2024/02/15

1/ Addition of two New Dynamic Events: Passing Options and Player Possessions

2/ Changes to Off-Ball runs Dynamic Event

New data points including

- Positions (LWB, LB, CD, ...) of the player in possession and the player performing the off-ball runs.
- Game states (winning, losing, drawing) and team scores at the moment of the event.
- last_defensive_line_height (distance of the last defender from their own goal).

Renaming of attributes

Former name	New name
player_possession_frame_start	associated_player_possession_frame_start
passing_option	predicted_passing_option
passing_option_start	passing_option_at_start
simultaneous_runs	n_simultaneous_runs
opponents_ahead_start	n_opponents_ahead_start
opponents_ahead_end	n_opponents_ahead_end
opponents_overtaken	n_opponents_overtaken

Give and Go

Previously we would qualify as give_and_go any off-ball runs that started within 2 sec after a pass from the very same player.

Based on feedback we have received we have decided to restrict it to off-ball runs of subtype behind, cross_receiver, overlap, pulling_half_space, pulling_wide, run_ahead_of_the_ball, underlap, support (for support run we also impose that it starts in the attacking third and in a half_space or the central channel).

As a consequence, coming_short, dropping_off and some support off-ball runs are not taken into account to determine whether there is a give and go or not.

Event filtering

Previously, we only considered off-ball runs where we were able to match the tracking data with the end of the associated player possession.

Now, we are including those where we did not, and we provide the field `is_player_possession_end_matched` to indicate whether the end of the possession was matched or not.

Tracking Data

Dynamic Events are generated using SkillCorner Tracking v3.

Many Dynamic event attributes are derived either directly or through machine learning models **from tracking data**.

Hence **the quality of Dynamic Events depends on the quality of SkillCorner Tracking v3**.

This quality can be affected by several factors, including:

- Video feed quality and associated production limitations (such as close-ups, replays, and players moving out of the camera's field of view)
- Camera location and stadium conditions
- SkillCorner ability to accurately detect the player and the ball, as well as read jersey numbers

To reduce the risk of delivering inaccurate information, we only provide Dynamic Events for matches that meet the following criteria:

- A quality index above 4 for both the players and the ball
- Successful matching of a sufficient number of Wyscout events with SkillCorner Tracking v3.

For more information on the quality of SkillCorner Tracking v3, please refer to the associated validation study.

Event Definitions

Player Possession

For an activity to be detected as a **Player Possession (PP)** the player needs to be in control of the ball, i.e. able to do a pass, shot or carry.

A player possession starts from the first touch of the player up to the last touch.

A one-touch is a player possession that lasts only one frame.

If a player is not in control of the ball then it does not qualify as a player possession.

Typically, if a player intercepts the ball without controlling it afterward, like for blocks, it does not count as a player possession.

Off-ball Run

For an activity to be detected as an (in possession) **Off-Ball Run (OBR)** it needs to have the following characteristics:

- lasts at least 0.7 seconds,
- be above $4.2 \text{ m/s} = 15 \text{ km/h}$,
- the player needs to have been on screen for at least 0.5 second during his run.

Additionally, the runner needs to be a passing option during or within 8 frames of his active run finishing or have received a pass after/during his run.

We extend the window as a player can make an active run, in anticipation of the ball carrier turning towards them to make a pass, but they may only become an option after they have stopped their run.

For more details on what off-ball runs are and which are the different types we detect, please refer to [this article](#).

We detect Off-Ball Runs occurring during a Player Possession i.e. when a player is in control of the ball.

As a consequence, we don't detect Off-Ball Runs occurring during set pieces or restarts.

Passing Option

For an activity to be detected as a **Passing Option (PO)** it needs to have the following characteristics:

- The player performing the event should be a highly likely target for a pass by the player in possession as predicted by our Receiver Model. It is reflected by the constraint that the player passing option score should be above 0.6.
- Lasts at least 0.3 seconds.

The passing option score is derived from our Receiver Model that predicts at each moment whether a player is a likely target for a pass. For further details read this [article](#).

Certain players while being close to the player in possession may not be identified as passing options since on average they are not targeted by the player in possession.

We also create a Passing Option event whenever a player has been targeted by a pass regardless of his passing option score.

If the player who was targeted by the pass did not have a passing option score above 0.6 for 0.3 seconds before being targeted, the event we create lasts 0.3 seconds and it ends with the frame of the pass from the player in possession.

We detect Passing Options occurring during a Player Possession i.e. when a player is in control of the ball.

As a consequence, we don't detect Passing Options occurring during set pieces or restarts.

To detect passing options for one-touch passes (that lasts only one frame), we extend the window to determine what are the passing options by two frames before and two frames after the first touch.

Relationship between events

Every Passing Option and every Off-Ball Run is associated with one and only one Player Possession.

It is the Player Possession when the event occurs.

A Passing Option or an Off-ball Run can start before and end after the player possession it is associated with but it can't overlap with two player possession.

Consequently, if a player is a passing option over several consecutive player possessions it will be represented by several passing option events (one for each player possession where the player is a passing option).

Every Off-Ball Run is associated with one and only one Passing Option.

For a player to be recorded as performing an Off-Ball Run, they need to have been a Passing Option at one point during his Off-Ball Run.

For a given Player Possession, if the player in possession attempted a pass, the Player Possession event references the Passing Option that was targeted.

Lastly the Player Possession events aggregates and references numerous data points related to the Passing Options and Off-Ball Runs that occurred during the Player Possession.

Merging Consecutive Events

If during the same player possession, two Passing Options are recorded for the same player with less than 0.5 sec between them, then the two events are merged into a single one.

If during the same player possession, two Off-Ball Runs are recorded for the same player with less than 0.5 sec between them, then the two events are merged into a single one.

Window extension

For any events that last less than 5 frames like a one touch pass, we use the 5 frames leading to the end of the event to compute speeds and trajectory angles.

Passing Moment Frame Selection

For each Passing Option and Off-ball Run event, we assign a passing_option_score, xthreat value, xpass_completion value and line breaking pass opportunity.

When a player is served a pass we compute the metrics at the moment of the pass.

When the player is not served, we compute the metrics at a (theoretical) passing moment.

The passing moment corresponds to the most likely passing moment the player could have been served the ball. It is the frame that, when passing_option_score is above 0.6, maximises:

$$\text{passing_option_score} \times \text{xthreat} \times \text{xpass_completion}$$

This calculation maximises the threat potential ($\text{xthreat} \times \text{xpass_completion}$) and weights it via the passing_option_score (likeliness of receiving the ball next).

We deliver the corresponding frame for Passing Option events under the attribute peak_passing_option_frame.

Model Used

Model used	Role	Associated Metrics
Receiver model (see details here)	A standardised score to measure the likelihood of a player being the target of a pass at a given frame. This model is used to determine whether a player is a passing option (to do so he needs to have passing_option_score > 0.6).	passing_option_score; passing_option; passing_option_start
xThreat model (see details here)	Probability for a goal to happen within 10 sec if a given player was to be the target of a complete pass at a given frame.	xthreat; dangerous_run; player_targeted_dangerous
Pass completion model (Graph Neural Network)	Probability of completing a pass to a player at a given frame.	xpass_completion; difficult_target; player_targeted_difficult
Run classification model (see details here)	Determines the type of off-ball run performed.	event_subtype

Direction of play and Pitch Coordinates

We deliver every player orientation dependent attribute - except attacking_side and attacking_side_id - assuming the team in possession is attacking from left to right.

It means that, for each period, we mirror the coordinates of the team that is actually attacking from right to left.

We consider that the center of the pitch coordinates are (0,0).

Coordinates are expressed in metres.

Event matching

In order to produce Dynamic events, we combine SkillCorner Tracking data with Wyscout Events.

Our ability to synchronise our tracking data with Wyscout events is critical and it also reflects our confidence in the accuracy of our dynamic events.

We check whether we are able to match:

- the start of a player possessions (this one does not exist in Wyscout, we have trained our own model to detect the beginning of a player possession)
- end of player possessions
- pass receptions

For every event we report whether we were able to match the start of the player possession, its end, and if relevant the previous pass and the next pass reception.

This matching is based on the distance between the player and the ball.

If we are not able to match any of these, the quality of the data associated with these particular moments can be lowered.

Empty Attribute Values

Several attributes including speed_avg, xy coordinates, or passing_option_score, xthreat, xpass_completion can sometimes be empty.

This is due to either the absence of enough information to deliver the metrics (e.g. when there is a very long close shot we don't provide tracking data after 10 sec) or, due to low confidence in the data (in particular for speed_avg).

Further details can be found in the description of the attributes.

Line Breaking Passes

For every Passing Option event (whether the player was served or not) we serve information about (potential) line breaks, especially which line is broken and how (through or around).

To identify line breaks we:

1. Determine if there is a defensive structure and the associated lines in place.
2. If there is a defensive structure, we determine whether these lines are (could have been) broken.

Defensive structure

We use the terminology defensive structure and not formation to reflect that these structures can be dynamic and evolve significantly during the same play.

Templates

We have a set of defensive structures *Templates* that correspond to the defensive structure we can detect.

Here are the *Templates* for a team of 11 defending players :

Here are the *Templates* for a team of 10 defending players (in case of a red card).

In case of 2 missing players we don't detect any defensive structure and we don't deliver line breaks.

Defensive Structure

For each Passing Option, we find which defensive structure *Template* fits best with the defending players positions during the pass if one occurs or at the passing moment if not.

For the Passing Options that were not served, we detect the defensive structure by looking at the defending teams players positions between:

- the passing moment
- and passing moment + 1 second

Serving Line Breaks

We define a line break situation as one where the defending team is organised and the state of play is not a counter attack or chaotic phase.

We have trained a model which evaluates how structured the defending team is using features like the speeds of the players and how well the defending team's structure fits a template.

As a result we rule out counter attacks, chaotic phases or situations where the defensive unit is highly disorganised and defensive lines cannot be clearly defined by using our machine learning model.

As a result we provide a field, organised_defense, which if True we deliver the defensive structure we identified and if False we do not provide a value.

Defensive Lines

If there is no structure then we don't define lines and we don't deliver line breaks.

If there is a structure then we define a line as a block of 2 or more players in the defensive structure.

Defensive Lines Naming Convention

The last defensive line is the one closest to the goal of the defending team.

The second last defensive line is the second closest to the defending team's goal.

If there are at least three lines, the first defensive line is the furthest from the defending team's goal.

A defensive line is not necessarily a straight line but rather a set of segments that links the players that are part of the same line.

5-3-2

If we have been able to identify a defensive structure and the associated defensive lines, the next step is to deliver line breaks.

Determining Whether a Line is Broken

For **successful passes**, we track the ball and player positions for each frame of the pass.

We determine if the line has been bypassed, either through or around the defenders. To determine if a line has been bypassed, we check whether the ball is at the left of the line at the frame of the pass, and at the right of the line at the moment of the reception.

As seen in the figure above, we do not simply draw a horizontal line; the line follows the organization of the players within the unit. Therefore, breaking a line does not necessarily mean surpassing the deepest defender. We choose this approach as it better reflects the actual football situation. In the example above, the receiver does not break the 'deepest line' but bypasses the central defender and receives the ball between the two wider center-backs. Given the space the attacker now has in front of them, it makes sense to say the line has been broken.

Then, we use a Machine Learning model to filter non relevant line breaks (for example passes that bypassed the line around with a very high angle, passes that bypassed the line through 2 defenders that are 30 metres away from each other, passes where the pass distance is very low, ...). This model is based on geometrical features about the pass (pass distance, pass angle, distance passer-line, distance receiver-line, ...).

For unsuccessful passes, we track the ball and player positions for each frame until the ball is intercepted or goes out of play. Then depending on whether the ball was intercepted closely, we can rely on the actual trajectory of the ball or infer it to detect line breaks. Then as for complete pass, we use the Machine Learning model to filter non relevant line breaks.

For Passing Options that were not targeted by a pass, we only know the passing moment using the passing moment equation. We infer the trajectory of the pass the player in

possession would have played to the passing option and determine what potential line break would have occurred. Once again, we then filter out non relevant line breaks using the same Machine Learning model as for previous situations.

The methodology used to infer ball trajectory is based on the player's speed and trajectory. We validated this methodology on actual successful passes. To do so we predicted whether a line break would have occurred on a set of actual successful passes and we reached an accuracy of 95%.

We have been asked several times whether we could predict if a pass would be played over a line. As of now we are not confident with predicting it accurately.

For every successful pass we deliver the high_pass flag that indicates whether the ball reached at least 1.8m during the pass. As a result, for every successful pass, one is able to further determine if a line breaking pass went around through and/or over the line(s).

For unsuccessful pass attempts, we indicate when the ball went above 1.8m (high_pass = True) but we cannot say it would not have. It means that the value of high_pass can only be True or None in this case.

Attributes specific consideration

Speeds

Every event has a speed average attribute.

To compute this speed average

- We need at least 5 frames where the player is detected.
- We apply data filtering to limit the risk of delivering inaccurate speed averages.

Consequently for some events the speed_avg attribute has no value.

It corresponds to cases where:

- We filtered out the speed_avg value.
- The player is not detected (especially when they are off-camera) during the whole event. This is often the case for passing options.

Here are some stats for a match:

Event Type	Number of events	% of Events with speed_avg values
Player Possession	1062	91.6%
Passing Options	2574	71.2%
Off Ball Run	486	97.9%

The average speed is not equal to the distance_covered divided by the event duration for several reasons

- This calculation would not work for one touch passes
- distance_covered takes into account the distance covered when the player is detected but also when he is extrapolated while speed is only computed based on the frame where the player is detected
- We apply filters to limit potential errors.

Lastly, we bucket speed_avg into speed bands.

Name of the Band	Speed
None	If no speed average is available
jogging	speed_avg below 15 km/h
running	speed_avg between 15 km/h and 20km/h
hsr	speed_avg between 20 km/h and 25km/h
sprinting	speed_avg above 25 km/h

Pass Range

We bucket pass distance into ranges as follow:

Ranges	Conditions
Short	less than 15m
Medium	between 15m and 30 m
Long	above 30m

By extension we also attribute a range to the distance between two players.

Angles and Directions

Most angles are expressed relative to the direction of attack.

We use degrees to measure angles.

Direction is always defined relative to the direction of attack, using a circle that spans from -180° to 180° (rotating anticlockwise). Here are the definitions for various directions:

- Forward: Corresponds to an angle between -45° and $+45^\circ$
- Backward: Corresponds to an angle below -135° or above 135°
- Sideway Left: Corresponds to an angle between 45° and 135°
- Sideway Right: Corresponds to an angle between -135° and -45°

Ahead, Same line and Behind

For some attributes like `location_to_player_in_possession_start` - which indicates the location of the player performing the event at its start compared to the player in possession - we have 3 possible values:

- Ahead: when the player is at least 3 metres ahead of the player in possession along the x axis.
- Same Line: when the player is between 3 m behind and 3 metres ahead of the player in possession along the x axis.
- Behind: when the player is at least 3 metres behind the player in possession along the x axis.

Forward momentum

With Forward Momentum the emphasis is on capturing players that perform an action centred around their first touch that results in a progressive outcome.

To do so we identify when a player is capable of initiating (sometimes continuing) a progressive move/action from his first touch (or the start of his possession), knowing that he received a pass from the back or from the side and that an opponent is at less than 6 metres from him at the moment of the first touch.

For instance it captures situations where the player is able to turn forward and move forward quickly.

We only capture forward momentum for player possessions that start within the central channel and the half space.

CSV File

The csv files consist of the list of all the Player Possession, Passing Option and Off-ball Runs detected during a match.

Each row corresponds to an event performed by a player from the team in possession.

Event Attributes

Metrics	Type	Description	Values	OBR	PO	PP
event_id	str	ID of the event. It is match specific.	e.g. 8_37	1	1	1
index	int	Sequence notation for the ordering of events within each match. If two events happen at the same time, we order them using their id.	e.g. 1	1	1	1
match_id	int	The ID of the match the event is associated with.	e.g. 32839	1	1	1
frame_start	int	Frame associated with the start of the event in SkillCorner extrapolated tracking data.	e.g. 304	1	1	1
frame_end	int	Frame associated to the end of the event in SkillCorner extrapolated tracking data.	e.g. 350	1	1	1
time_start	times tamp	Time in the match when the event starts, recorded to the millisecond. Second period starts at 00:45:00.	e.g. 00:00:06.293	1	1	1
time_end	times tamp	Time in the match when the event ends, recorded to the millisecond. Second period starts at 00:45:00.	e.g. 00:00:10.331	1	1	1
minute_start	int	The minutes on the clock at the time of this event. Resets to 45 at half-time, 90 at the start of extra time etc.	e.g. 25	1	1	1
second_start	int	The seconds part of the timestamp.	e.g. 10	1	1	1
duration	float	Number of seconds the event lasts.	e.g. 4.1	1	1	1
period	int	An identified identifier for the period of the match when the event happens.	- 1: first half - 2: second half - 3: first extratime - 4: second extratime	1	1	1

Metrics	Type	Description	Values	OBR	PO	PP
			- 5: penalty shootout			
attacking_side_id	int		- 1 (left_to_right) - 2 (right_to_left)	1	1	1

peak_passing_option_frame	int	<p>Frame considered as the passing moment.</p> <p>If the passing option is targeted it is the actual frame of the pass otherwise it is estimated (when $xR.xP.xT$ is maximal and $xR \geq 0.6$).</p>	e.g. 1662	0	1	0
passing_option_at_player_possession_start	bool	<p>TRUE if the player was a passing option during the first 0.5 seconds of the associated player possession.</p> <p>Else FALSE.</p>	<ul style="list-style-type: none"> - TRUE - FALSE 	1	1	0
n_simultaneous_runs	int	The number of off-ball runs that overlap with the current event or that happen less than 5 frames before or after it.	e.g. 2	1	0	0

Metrics	Type	Description	Values	OBR	PO	PP
give_and_go	bool	TRUE if the player starts his off-ball run less than 2 sec after passing the ball. Else FALSE. Applies only to off-ball runs of subtype behind, cross_receiver, overlap, pulling_half_space, pulling_wide, run_ahead_of_the_ball, underlap, support (for support run we also impose that it starts in the attacking third and in a half_space or the central channel).	- TRUE - FALSE	1	0	0
intended_run_behind	bool	None if the off-ball run is not a run in behind (event_subtype <> "behind"). TRUE if a player shows intention to run behind the defensive line. This captures attackers who may hold their run to not be offside, or runs where players are tracked by a defender but there is intent to receive behind the defensive line. Else FALSE. For example a player does break the defensive line.	- None - TRUE - FALSE	1	0	0
push_defensive_line	bool	None if the off-ball run is not a run in behind (event_subtype <> "behind"). TRUE if the last defender moves back at least 10 m back during the off-ball run (between time_start and time_end). Else FALSE.	- None - TRUE - FALSE	1	0	0
break_defensive_line	bool	None if the off-ball run is not a run in behind (event_subtype <> "behind"). TRUE if between end_time - 1s and end_time + 1s, there is at least a frame when the player is 1 meter behind the last defender. Else FALSE.	- None - TRUE - FALSE	1	0	0
passing_option_at_start	bool	TRUE if the player was a passing option during the first 0.5 seconds of the off-ball run. Else FALSE.	- TRUE - FALSE	1	0	0
n_simultaneous_passing_options	int	The number of passing options that overlap with the current event or that happen less than 5 frames before or after it.	e.g. 3	0	1	0
passing_option_at_pass_moment	bool	TRUE if the player is a passing option during the 0.5 seconds before the player in possession attempts a pass (decision frame). Else FALSE.	- TRUE - FALSE	0	1	0
n_opponents_ahead_end	int	The number of opponents (goalkeeper excluded) between the player and the opposing team goal at the end of the event.	e.g. 3	1	0	1
n_opponents_ahead_start	int	The number of opponents (goalkeeper excluded) between the player and the opposing team goal at the start of the event.	e.g. 5	1	0	1

Metrics	Type	Description	Values	OBR	PO	PP
n_opponents_overtaken	int	Difference between opponents_ahead_start and opponents_ahead_end.	e.g. 2	1	0	1
is_player_possession_start_matched	bool	TRUE if we are able to match the start of the player possession with the tracking data based on the player and ball position. Else FALSE	- TRUE - FALSE	1	1	1
is_player_possession_end_matched	bool	TRUE if we are able to match the end of the player possession with the tracking data based on the player and ball position. Else FALSE	- TRUE - FALSE	1	1	1
is_previous_pass_matched	bool	<p>None if the player possession did not start with a pass reception.</p> <p>If the player possession started with a pass reception,</p> <ul style="list-style-type: none"> - TRUE if the reception was matched with the tracking. - Else FALSE. <p>Then it makes sense to look at all the fields that concern the pass received ("pass_distance_received", ...).</p>	- TRUE - FALSE - None	0	0	1
is_pass_reception_matched	bool	<p>None if the player possession did not end with a complete pass.</p> <p>If the player possession ended with a complete pass,</p> <ul style="list-style-type: none"> - TRUE if the reception was matched with the tracking - Else FALSE. <p>Then it makes sense to look at all the fields that concern the pass ("pass_angle", ...).</p>	- TRUE - FALSE - None	1	1	1
fully_extrapolated	bool	TRUE if the player is never detected in the video during the whole event meaning that his position is totally predicted by our extrapolation model (either because the player is not in the field of view of the camera or he is not detected). ELSE FALSE	- TRUE - FALSE	0	1	1
